HYDROSEED

## WATERING

Lightly water your newly hydroseeded area several times a day depending on weather and irrigation coverage. Exercise caution and do not over water. Avoid pooling water that could wash away the newly seeded area.

After approximately 7-10 days you should begin to see grass sprouts. Bare spots are typical but could also be an indication of lack of water.

## FERTILIZING

The vegetation will utilize fertilizer applied at the time of installation in the first 4-5 weeks. After this period you will need to fertilize again. You should check with your local nursery for fertilizing information.

## MOWING

Once your grass is approximately 2 to 2-1/2 inches high, it is time for its first mowing (approximately three weeks). It is important to ensure your mower blades are sharp. Dull blades can tear the new blades of grass which could cause stress or disease resulting in death of the new vegetation. Never take more than 1/4" off of the new blades of grass. Do not collect the grass clippings after the first mowing, instead, allow them to biodegrade within the new turf. Leaving the clippings aids in nourishing the soil and vegetation while accelerating plant development. If more than two inches has been cut off of the top, be sure to remove grass clippings from lawn. Changing the direction you mow your lawn each time is recommended. For instance, if you mow from left to right the first mowing, mow from top to bottom the next time.

## REMEMBER

Once your lawn is hydroseeded, properly watered and warmed by the sun, watch for the appearance of weeds. If you spot weed growth it is very important to remove them quickly or they will compete with your grass seed for water and nutrients. Although your new lawn may appear established, at this stage it is still young. It will take several months before your lawn is ready for the stress of hot and cold temperatures. Remember to maintain the proper lawn care best practices for maximum results.
